52 Notation

- 53 c : a (vector of) constant(s)
- 54 $\lambda \in \mathbb{R}$: a scalar
- 55 $n \in \mathcal{N}$: sample size
- 56 i, j are indices in $\{1, \dots, n\}$
- 57 $x \in \mathbb{R}^n$: covariate in 1-dim interpolation setting
- 58 $w \in \mathbb{R}^n$: a vector of weights for each location x
- 59 $y \in \mathbb{R}^n$: response in 1-dim interpolation setting
- 60 $\hat{y} \in \mathbb{R}^n$: estimate of y
- 61 $r \in \mathbb{R}^n$: residuals given by $y - \hat{y}$
- 62 Pixel: A pixel describes a specific location in a field. It has the size of 10 x 10 meters
63 and coincides with the resolution (and location) of the sentinel-2 pixels. Such pixels are
64 illustrated in figure ??.
- 65 P_t : this describes the observed data (weather and spectral bands) at time t and the location
66 of one pixel.
- 67 P : a pixel. We see it as a collection of all the observations at the specified location within
68 one season. More formally, $P := \{P_t | t \text{ is a valid sample time within a defined season}\}$
- 69 SCL: scene classification layer. This indicates what one can expect at a pixel at a sampled
70 time. For an overview c.f. table 2.1
- 71 P^{SCL45} : similar to P but we only consider observations which belong to the classes 4 and
72 5. This is used done to get a subset of observations which are less contaminated by clouds
73 and shadows.
- 74 NDVI: normalized vegetation difference index
- 75 DAS: days after sowing
- 76 GDD: growing degree days – cumulative sum of (temperature – threshold)⁺

115 **Chapter 3**

116 **Interpolation Methods**

117 In this section, we take a closer look at several interpolation methods, which will be used
118 to interpolate and smooth the NDVI time series.

119 First, we give a brief overview in table [3.1](#).

120 Second, we define the general setting and discuss a general approach to make the interpo-
121 lation more robust (i.e. reduce the impact of outliers).

122 Later, we introduce and discuss each method.

123 Then, we try to extract the main ingredients of each method to forge our own one.

124 Finally, using leave-one-out cross validation, we tune the parameters (where necessary)
125 and get a first idea of the performance of each method.

126 **3.1 Setting**

We are given data in the form of (x_i, Y_i) for $i = 1, \dots, n$. Assume that it can be represented by

$$Y_i = m(x_i) + \varepsilon_i,$$

where ε_i is some noise and $m : \mathbb{R} \rightarrow \mathbb{R}$ being some (parametric or non-parametric) function.
If we assume that $\varepsilon_1, \dots, \varepsilon_n$ i.i.d. with $\mathbb{E}[\varepsilon_i] = 0$ then

$$m(x) = \mathbb{E}[Y | x]$$

127 Different assumptions on m will lead to the following methods:

128 **3.2 XXX DAS vs GDD**

129 **3.3 Robustify**

130 Now we discuss a general approach of how to robustify an interpolation. The main idea
131 is to give less weight to observations which have high residuals after the initial (or if we
132 reiterate, the last) fit.

Table 3.1: A short summary of the studied interpolation methods

| | assumptions | pros | cons | weights | bounded |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|----------------|----------------|
| Savitzky-Golay filter | <ul style="list-style-type: none"> - high frequencies are noise (low.pass filter) - equidistant points - local polynomials | <ul style="list-style-type: none"> - computationally very fast | <ul style="list-style-type: none"> - cannot deal natively with missing data (need some interpolation) | no | mostly |
| SG NDVI | <ul style="list-style-type: none"> + upper envelope - vegetation cannot grow faster than some slope | <ul style="list-style-type: none"> - biological knowledge edge | <ul style="list-style-type: none"> - bad “upper envelope” since weights are not used for the estimation itself | (no) | mostly |
| Loess | <ul style="list-style-type: none"> - local polynomial with points closer to the estimated point are more important | <ul style="list-style-type: none"> - flexible - generalization of SG - weighting function makes intuitive sense | <ul style="list-style-type: none"> - computationally expensive | yes | mostly |
| Smoothing Splines | <ul style="list-style-type: none"> - 2cd derivative of function is integrable | <ul style="list-style-type: none"> - intuitive meaning of penalty - general assumptions - flexible shape | <ul style="list-style-type: none"> - unbounded | yes | no |
| B-Splines (Smoothed) | <ul style="list-style-type: none"> - function can be approximated by a linear combination of B-splines basis functions | <ul style="list-style-type: none"> - general assumption - flexible shape | <ul style="list-style-type: none"> - unbounded - no intuitive meaning for smoothing | | no |
| (Gaussian) Kernel Smoothing | | <ul style="list-style-type: none"> - simple - general assumptions | <ul style="list-style-type: none"> - bandwidth: fails if there are big data-gaps | yes | yes |
| Double-Logistic | <ul style="list-style-type: none"> - function first increases then decreases - ndvi has a minimal value | <ul style="list-style-type: none"> - good for evergreen plants (if snow masks ndvi) - upper envelope | <ul style="list-style-type: none"> - parameterestimation can go seriously wrong - strange behaviour for long data-gaps | yes | mostly |
| Universal Kriging | <ul style="list-style-type: none"> - function is a realization of a stationary gaussian process | <ul style="list-style-type: none"> - informative parameters - flexible | <ul style="list-style-type: none"> - regression to the mean - assumptions clearly not met | yes | mostly |

133 Even though the procedure is taken from the robust version of the LOESS smoother (c.f.
 134 section 3.5.4 and [Cleveland \(Cleveland\)](#)), we discuss it now because we will apply it also
 135 to other interpolation methods.

136 XXX¹

Before we describe the procedure, we define a function which will determine the weight given to each observation such that observations with large scaled residuals will have less weight. That is the bisquare function B :

$$B(x) := \begin{cases} (1 - x^2)^2, & \text{if } |x| < 1 \\ 0, & \text{else} \end{cases}$$

137 Now, we do something similar to what is done in iteratively reweighted least squares. After
 138 an initial interpolation, update the weights of each observation with

$$w_i^{\text{new}} := w_i^{\text{old}} B\left(\frac{|r_i|}{6 \text{mad}(r_1, \dots, r_n)}\right) \quad (3.3.0.1)$$

139 where $r_i = y_i - \hat{y}_i$ denotes the residuals. We can iterate this reweighting and stop after
 140 several steps or when the change of the values is smaller than some tolerance.

141 Examples of such iterative fits are illustrated in the figures [3.4](#) [3.5](#), [3.6](#), [3.4](#) and [3.7](#).

142 3.3.1 XXX Our Adjustment:

Since we usually observe outliers with negative residuals we decide to divide the negative residuals by two(XXX) before updating the weights. Furthermore, we want to prevent low-weighted observations to corrupt our estimation of scale (the median) and thus we use the weighted median. This can be defined as

$$\text{med}_{\text{weighted}}(r, w) := \arg \min_{\lambda \in \mathbb{R}} \sum_{i=1}^n |r_i w_i - \lambda|$$

143 for $r, w \in \mathbb{R}^n$

144 3.4 Parametric Regression

145 Parametric Curve estimation tries to fit a parametric function (e.g. a Gaussian function
 146 with parameter μ and σ) to a dataset. In the following, we introduce 2 such parametric
 147 approaches.

148 Optimization Issues

149 Since we aim to minimize the residuals sum of squares over 5 (or 6) parameters, we try
 150 to solve a non-convex optimization problem. Thus, the algorithm² either struggles to find
 151 the global minimum or fails to converge. This was fixed by providing for each parameter
 152 reasonable initial values and generous bounds (which match our experience).

¹Note that due to using the median for the normalization, we gain a breakdown point of 50% for outliers in y .

²We used the python function `scipy.optimize.curve_fit`

153 **3.4.1 Double Logistic**

154 The Double Logistic smoothing as described in [Beck, Atzberger, Høgda, Johansen, and Skidmore \(Beck et al.\)](#) heavily relies on shape assumptions of the fitted curve (i.e. the
 155 NDVI time series).

156 Assumptions:

- 157 — There is a minimum NDVI level Y_{\min} in the winter (e.g. due to evergreen plants),
 158 which might be masked by snow. This can be estimated beforehand, taking into
 159 several years into account.
- 160 — The growth cycle can be divided into an increase and a decrease period, where
 161 the time series follows a logistic function. The maximum increase (or decrease) is
 162 observed at t_0 (or t_1) with a slope of d_0 (or d_1).

163 The equation of the double-logistic fit is given by:

$$Y(t) = Y_{\min} + (Y_{\max} - Y_{\min}) \left(\frac{1}{1 + e^{-d_0(t-t_0)}} + \frac{1}{1 + e^{-d_1(t-t_1)}} - 1 \right)$$

164 Where the five free parameters: Y_{\max} , d_0 , d_1 , t_0 , t_1 are initially estimated by least squares.
 165 Such fit can be seen in figure [3.1](#).

166 Similar as for the Savitzky-Golay Filter (c.f. section [3.5.3](#)) we reestimate (only once) the
 167 parameters by giving less weight to the overestimated observations and more weight to
 168 the underestimated observations³.

| Pros | Cons |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> — Incorporates subject specific knowledge in the case of evergreen plants covered in snow. — Optimized parameters have an intuitive meaning. | <ul style="list-style-type: none"> — Strong shape assumptions on the NDVI curve. — Parameter optimization might go wrong. This can be mitigated to some extent to provide bounds for the parameters — Strange behavior in regions with little observations. (cf. figure 3.1) |

169 **3.4.2 Fourier Approximation**

Similar as in section [3.4.1](#) we fit a parametric curve to the data by least squares. Here we take the second order Fourier series:

$$\text{NDVI}(t) = \sum_{j=0}^2 a_j \times \cos(j \times \Phi_t) + b_j \times \sin(j \times \Phi_t)$$

170 where $\Phi = 2\pi \times (t - 1)/n$.

³For the details on the weights we refer to [Beck, Atzberger, Høgda, Johansen, and Skidmore \(Beck et al.\)](#)

| Pros | Cons |
|--------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| — Assumption of periodicity can be helpful if we are modelling multiyear grow cycles | — Bad behavior in regions with little data (cf. figure 3.1) |
| — Flexible curve shape | — Hard to interpret estimated parameters — Parameter estimation can go wrong. Introducing bounds can help. |

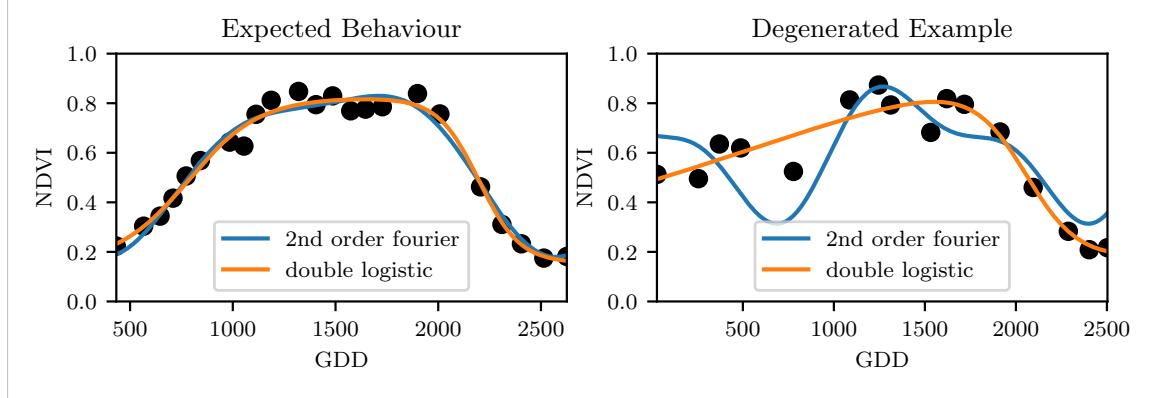

Figure 3.1: Here we observe the nice fitting possibilities of the two parametric methods but notice also some misbehavior

171 3.5 Non-Parametric Regression

172 In non-parametric curve estimation, we no longer demand our curve to be fully determined
 173 by several parameters, but we allow it to also depend on the data. That said, we might
 174 still use some tuning-parameters sometimes.

175 3.5.1 Kernel Regression

176 As described previously, we would like to estimate

$$\mathbb{E}[Y \mid X = x] = \int_{\mathbb{R}} y f_{Y|X}(y \mid x) dy = \frac{\int_{\mathbb{R}} y f_{X,Y}(x,y) dy}{f_X(x)}, \quad (3.5.1.1)$$

where $f_{Y|X}, f_{X,Y}, f_X$ denote the conditional, joint and marginal densities. This can be done with a kernel K :

$$\hat{f}_X(x) = \frac{\sum_{i=1}^n K\left(\frac{x-x_i}{h}\right)}{nh}, \quad \hat{f}_{X,Y}(x,y) = \frac{\sum_{i=1}^n K\left(\frac{x-x_i}{h}\right) K\left(\frac{y-Y_i}{h}\right)}{nh^2}$$

By plugging the above into equation 3.5.1.1 we arrive at the *Nadaraya-Watson* kernel estimator:

$$\hat{m}(x) = \frac{\sum_{i=1}^n K\left((x - x_i)/h\right) Y_i}{\sum_{i=1}^n K\left((x - x_i)/h\right)}$$

177 **Examples:** Normal, Box For local bandwidth selection see Brockmann et al. (1993)
 178 XXX

| Pros | Cons |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> — flexible due to different possible kernels — can be assigned degrees of freedom (trace of the hat-matrix) — estimation of the noise variance $\hat{\sigma}_\varepsilon^2$ (XXX c.f. CompStat 3.2.2) | <ul style="list-style-type: none"> — if the $x \mapsto K(x)$ is not continuous, \hat{m} isn't either — choice of bandwidth, especially if x_i are not equidistant. |

3.5.2 Kriging

Kriging was developed in geostatistics to deal with autocorrelation of the response variable at nearby points. By applying the notion that two spectral indices which are (timewise) close should also take similar values, we justify the application of Kriging. In the end, we would like to fit a smooth Gaussian process to the data. For this subsection, we will follow Diggle and Ribeiro ([dig](#)).

Definitions and Assumptions

A *Gaussian Process* $\{S(t) : t \in \mathbb{R}\}$ is a stochastic process if $(S(t_1), \dots, S(t_k))$ has a multivariate Gaussian distribution for every collection of times t_1, \dots, t_k . S can be fully characterized by the mean $\mu(t) := E[S(t)]$ and its covariance function $\gamma(t, t') = \text{Cov}(S(t), S(t'))$

Assumption: We will assume the Gaussian process to be stationary. That is for $\mu(t)$ to be constant in t and $\gamma(t, t')$ to depend only on $h = t - t'$. Thus, we will write in the following only $\gamma(h)$.⁴

We also define the variogram of a Gaussian process as

$$V(h) := V(t, t + h) := \frac{1}{2} \text{Var}(S(t) - S(t + h)) = (\gamma(0))^2 (1 - \text{corr}(S(t), S(t + h)))$$

And decide to use a Gaussian Variogram defined by

$$V(h) = p \cdot \left(1 - e^{-\frac{h^2}{(\frac{4}{7}r)^2}} \right) + n,$$

where h is the distance, n is the nugget, r is the range and p is the partial sill visualized in figure 3.2.⁵

| Pros | Cons |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> — It is a well-studied method. — Parameters have an intuitive meaning. — Flexible covariance structure. | <ul style="list-style-type: none"> — Regression to the mean. — Violated assumption of constant mean and constant variance. Thus, the NDVI is not a stationary process. — Skewness of errors is not taken into account. |

⁴Note that the process is also *isotropic* (i.e. $\gamma(h) = \gamma(\|h\|)$) since we are in a one-dimensional setting and the covariance is symmetric.

⁵Strictly speaking we use a scaled version of the variogram. Thus, only the ratio of p/n matters.

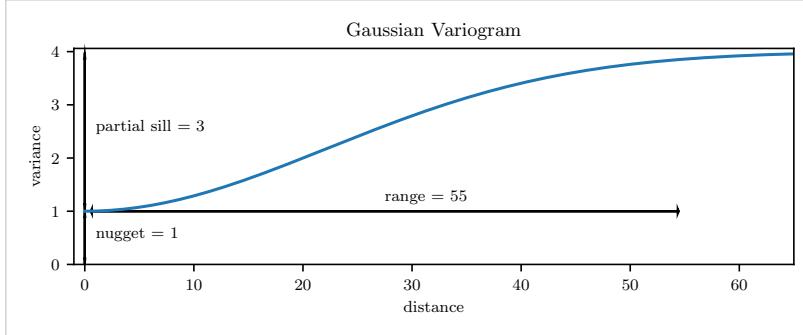

Figure 3.2: Gaussian Variogram with nugget=1, partial sill=3, range=55

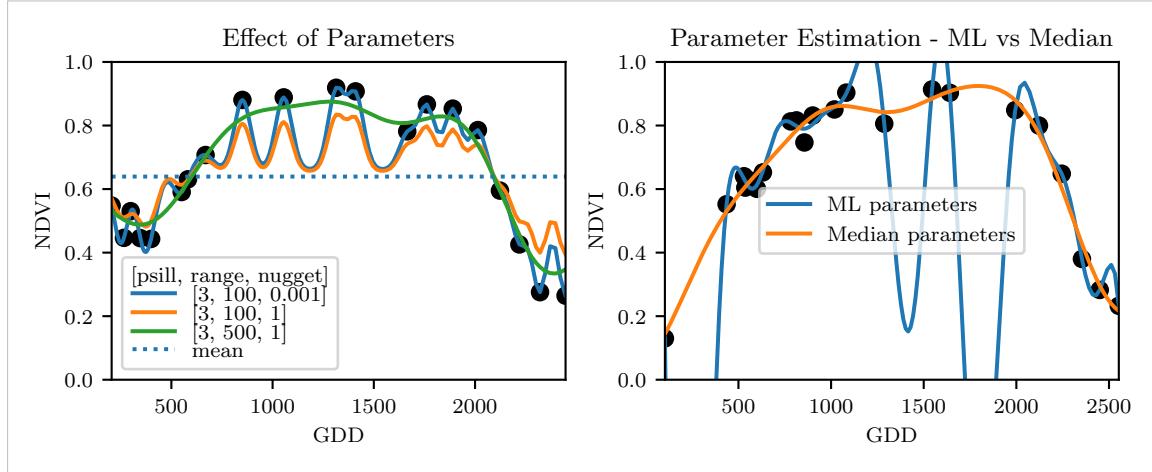

Figure 3.3: On the left, we see how the interpolation change if we increase the nugget and the range parameter. On the right we compare two kriging interpolations, where one takes parameters by numerically maximizing the (which results in a very small nugget) and the other takes the median of many such numerical optimizations.

194 3.5.3 Savitzky-Golay Filter (SG Filter)

The *Savitzky-Golay Filter*, introduced in [Savitzky and Golay](#) ([Savitzky and Golay](#)) is a technique in signal processing and can be used to filter out high frequencies (low-pass filter) as argued in [Schafer](#) ([Schafer](#)). Furthermore, it also can be used for smoothing by filtering high frequency noise while keeping the low frequency signal. First, we choose a window size m . Then, for each point, $j \in \{m, m+1, \dots, n-m\}$ we fit a polynomial of degree k by:

$$\hat{y}_j = \min_{p \in P_k} \sum_{i=-m}^m (p(x_{j+i}) - y_{j+i})^2,$$

195 where P_k denotes the Polynomials of degree k over \mathbb{R} .

For equidistant points this can efficiently be calculated by

$$\hat{y}_j = \sum_{i=-m}^m c_i y_{j+i},$$

196 where the c_i are only dependent on the m and k and are tabulated in the original paper.

197 **Adaptation to the NDVI**

198 In a rather famous paper [Chen, Jönsson, Tamura, Gu, Matsushita, and Eklundh \(Chen et al.\)](#) a “robust” method based on the Savitzky-Golay has been used. The method is
 199 based on the assumption that due to atmospheric effects the observed NDVI tends to be
 200 underestimated and that it cannot increase too quickly⁶.
 201

202 **Algorithm:**

- 203 i.) Remove points which are labeled as cloudy.
- 204 ii.) Remove points which would indicate an increase greater than 0.4 within 20 days.
- 205 iii.) Linearly interpolate to obtain an equidistant time series X^0 .
- 206 iv.) Apply the Savitzky-Golay Filter to obtain a new time series X^1 .
- 207 v.) Update X^1 by applying again a Savitzky-Golay Filter. Repeat this until $w^T |X^1 - X^0|$
 208 stops decreasing, where w is a weight vector with $w_i = \min\left(1, 1 - \frac{X_i^1 - X_i^0}{\max_i \|X_i^1 - X_i^0\|}\right)$.
 209 This reduces the penalty introduced by outliers⁷ and by repeating this step we approach the “upper NDVI envelope”.

| Pros | Cons |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> — Popular technique in signal processing. — Efficient calculation for equidistant points. — Upper envelope matches intuition for the NDVI. Therefore, it is robust against outliers with small values. | <ul style="list-style-type: none"> — No natural way of how to estimate points which are not in the data. — Not generalizable to other spectral indices. — Linear interpolation to account for missing data might be not appropriate. — No smooth interpolation between two measurements. |

211 **Extension: Spatial-Temporal-Savitzky-Golay Filter**

212 One notable adaptation of the Savitzky-Golay is the presented by [Cao, Chen, Shen, Chen, Zhou, Wang, and Yang \(Cao et al.\)](#). The key difference is the additional assumption of the
 213 cloud cover being discontinuous and that we can improve by looking at adjacent pixels⁸.
 214 Because we are working with rather high resolution satellite data, and we need the variance
 215 in the predictors, we will waive this extension.

217 **3.5.4 Locally Weighted Regression (LOESS)**

218 Introduced by : [Cleveland \(Cleveland\)](#) implemented here [Cappellari, McDermid, Alatalo, Blitz, Bois, Bournaud, Bureau, Crocker, Davies, Davis, de Zeeuw, Duc, Emsellem, Khochfar, Krajnović, Kuntschner, Morganti, Naab, Oosterloo, Sarzi, Scott, Serra, Weijmans, and Young \(Cappellari et al.\)](#)

⁶The latter is argued by the biological impossibility of such fast vegetation changes

⁷Here we call a point i an outlier if $X_i^0 < X_i^1$.

⁸Here, we say that a pixel is adjacent if it is the same pixel but from a different year (keeping the same day of the year) or (if not enough of such temporal-adjacent pixel are found) it is spatially adjacent

222 The Locally Weighted Regression (LOESS) can be understood as a generalization of the
 223 Savitzky-Golay Filter (c.f. sec. 3.5.3).

Given a proportion $\alpha \in (0, 1]$, we estimate each y_i separately by fitting a polynomial of order d by weighted least squares. The weights are (usually) defined by

$$w_i(x_j) = \begin{cases} \left(1 - \left(\frac{x_j}{h_i}\right)^3\right)^3, & \text{for } |x_j| < h_i, \\ 0, & \text{for } |x_j| \geq h_i \end{cases}$$

224 where h_i is the minimal distance such that $\lceil \alpha n \rceil$ observations are in the ball $B_{h_i}(x_i)$.⁹ So
 225 for each y_i we only consider a proportion α of the observations.

226 How does the Robust LOESS differ from the SG Filter?

227 The LOESS smoother takes a fraction of points instead of a fixed number and therefore
 228 automatically adapts to the size of the data we wish to interpolate. However, we run
 229 into the danger of considering too little observations, since the estimation breaks down if
 230 $\lceil \alpha n \rceil < d + 1$. Furthermore, LOESS gives less weight to points further away. This yields a
 231 "smoother" estimate, since when we slide the window (e.g. for estimating the next value)
 232 an influential point at the border does not suddenly get zero weight from being weighted
 233 equally before. Finally, the LOESS also can be used for non-equidistant data and allows
 234 for arbitrary interpolation.

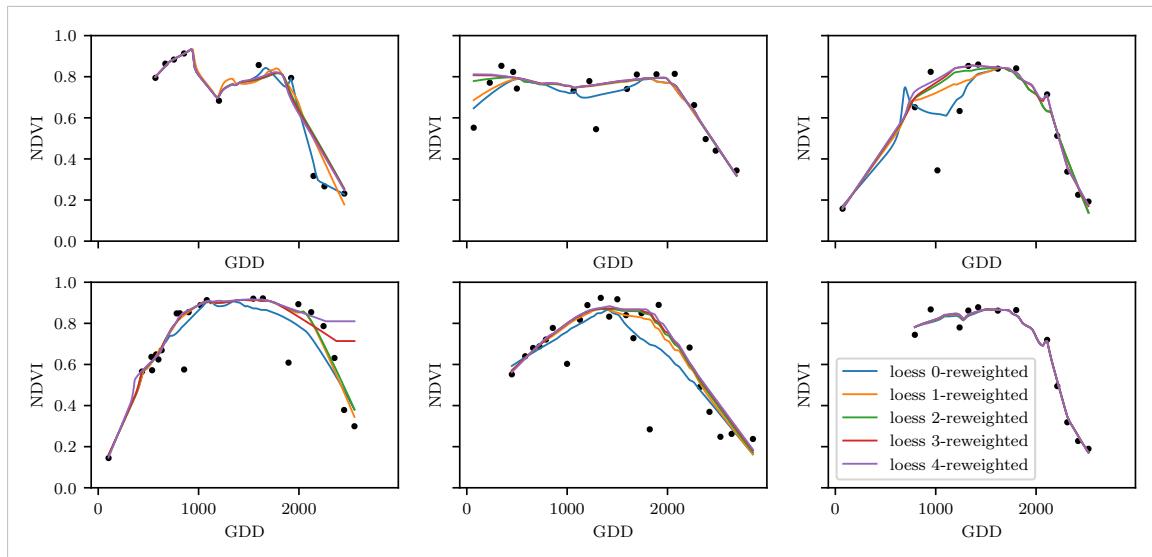

Figure 3.4: The LOESS smoother fitted to different (SCL45) NDVI time series. Iterations of a robustifying refit (as indicated in section 3.3) are also displayed

⁹If too many weights are set to zero, we might end up considering not enough observations and thus get a singular design-matrix (for the least squares estimation). Therefore, we substitute h_i with $1.01h_i$, so that the observation on the boundary of $B_{h_i}(x_i)$ does not get completely ignored.

| Pros | Cons |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| — Flexible generalization of Savitzky-Golay | — The nature of local regression might lead to surprising estimates (no smoothness guarantees for the second derivative) |
| — arbitrary interpolation possible | — Multiple XXXXXXx |
| — Intuitive parameters | |

235 **3.5.5 B-splines**

from [Lyche and Mørken](#) ([Lyche and Mørken](#))

$$S(x) = \sum_{j=0}^{n-1} c_j B_{j,k;t}(x)$$

$$\begin{aligned} B_{i,0}(x) &= 1, \text{ if } t_i \leq x < t_{i+1}, \text{ otherwise } 0 \\ B_{i,k}(x) &= \frac{x-t_i}{t_{i+k}-t_i} B_{i,k-1}(x) + \frac{t_{i+k+1}-x}{t_{i+k+1}-t_{i+1}} B_{i+1,k-1}(x) \end{aligned}$$

236 **Smoothing:** We can relax the constraint that we have to perfectly interpolate. Thus, we use the minimum number of knots¹⁰ such that: $\sum_{i=1}^n (w(y_i - \hat{y}_i))^2 \leq s$

| Pros | Cons |
|----------------------------------------------------|--------------------------------------------------------------------------------------------|
| — can be assigned degrees of freedom | — smoothing process does not translate well to a interpretation (unlike smoothing splines) |
| — extendable to "smooth" version | |
| — performs also well if points are not equidistant | — choice of smoothing parameter s |

237

238 **3.5.6 Natural Smoothing Splines**

Let \mathcal{F} be the Sobolev space (the space of functions of which the second derivative is integrable). Then the unique¹¹ minimizer

$$\hat{m} := \arg \min_{f \in \mathcal{F}} \sum_{i=1}^n (Y_i - f(x_i))^2 + \lambda \int f''(x)^2 dx$$

239 is a natural¹² cubic spline (i.e. a piecewise cubic polynomial function). The objective
240 function has an intuitive meaning, as to avoid lateral acceleration it is desirable to move
241 the steering wheel as little as possible, when driving a car.

242 **3.5.7 XXX Whittaker Smoother**

243 XXX

¹⁰SciPy uses FITPACK and DFITPACK, the documentation suggests that smoothness is achieved by reducing the number knots used

¹¹Strictly speaking it is only unique for $\lambda > 0$

¹²It is called natural since it is affine outside the data range ($\forall x \notin [x_1, x_n] : \hat{m}''(x) = 0$)

| Pros | Cons |
|--------------------------------------------------------------------------------------|--------------------|
| — can be assigned degrees of freedom (trace of the hat-matrix) | — choose λ |
| — efficient estimation (closed form solution) | |
| — intuitive penalty (we don't want the function to be too "wobbly" — change slopes) | |
| — performs also well if points are not equidistant | |
| — fixes the Runge's phenomenon (fluctuation of high degree polynomial interpolation) | |

244 **3.6 Tuning parameter estimation**

245 lots of cross validation

246 what is the best? RMSE is bad, since we know that outliers are present optimizing w.r.t
247 different statistics

248 ?plot with different densities for each statistic

249 **3.7 Robustification – Recap**

250 introduced in section ?? we want to review it

251 robustifieng from loess -> lets try it with all. Result in figures ...

252 issues when reiterating often (we lose some points completely)

253 from pictures ... we get that one

254 **3.7.1 Upper Envelope Approach - Penalty for negative residuals**

255 discussion of idea, and explanation why we did not use it (arbitrary choice)

256 **3.8 Performance Assessment**

257 **TEMP — Figures**

Table 3.2: Performance comparison of different interpolation methods measured with various statistics. Considering only SCL45 points, we get the out-of-bag estimates using the given interpolation method. Consequently, we compute the absolute (value of the) residuals and apply the given statistic to it.

258 **Chapter 4**

259 **NDVI Correction / Improve NDVI
260 Data**

261 Let's remind ourselves that the data from the Sentinel-2 is equipped with a scene classi-
262 fication layer (SCL) and we therefore have some information of what is observed at each
263 pixel for each sampled time (c.f. table 2.1). In this chapter we would like to improve
264 the observed NDVI values by using more information than just the two bands used to
265 calculate the NDVI (B4 and B8).

266 **4.1 Considering other SCL Classes**

267 In figure 4.1 we see for example that some blue points¹ follow the interpolated line closely
268 and that they might be useful in improving an interpolation fit.

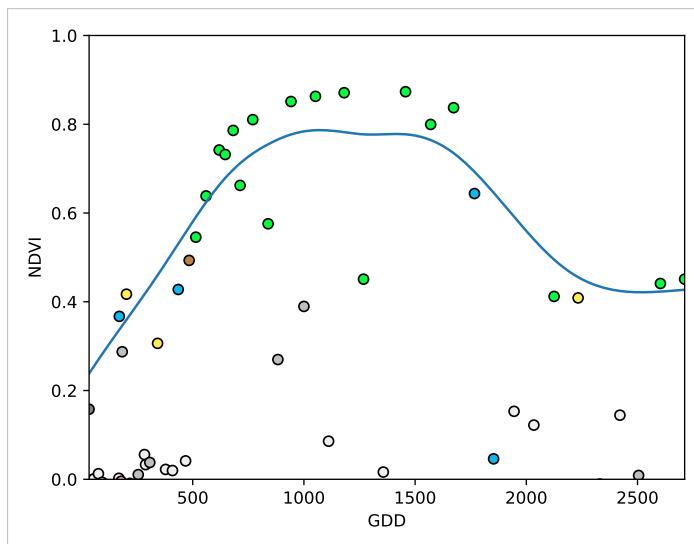

Figure 4.1: A smoothing splines fit considering green and yellow points (SCL45)

269 To get an impression whether there is some useful information contained in the remaining
270 SCL-classes (all except 4 and 5) we would like to compare the observed NDVI with the

¹The blue points correspond to the SCL-class 10: Thin cirrus clouds

271 true NDVI. But since we do not have any ground truth data, we will make the following
 272 assumption:

273 **Definition 4.1.0.1.** *XXXAssumption (true NDVI)* *The true NDVI value at time t can be*
 274 *successfully estimated by out-of-bag interpolation using high quality observations. That is*
 275 *the interpolated value (using XXX) considering the points $P^{SCL45} \setminus P_t$. In the following,*
 276 *we will call this estimate the “true”-NDVI*

277 shall pair every observed NDVI value with its out-of-bag-estimate. Then for each category
 278 we collect all pairs and create a scatter plot in fig 4.2XXXXXXXXXXXXXX

- 279 i.) For each pixel and for each observation (every SCL-class):
 280 estimate the NDVI value (via out-of-the-box interpolation²)
- 281 ii.)

282 4.2 XXX Correction

283 roadmap ... (intuition, data-table, ml-methods, uncertainty, refit and evaluation)

284 4.2.1 XXX idea -and- stepwise plots

285 4.2.2 XXX data-table-construction

286 XXX discussion about choosen covariates: list of things we considered but rejected +
 287 reasoning -> no weather to keep it general even though we have it implemeted

288 4.2.3 XXX ml-methods

289 4.2.4 XXX Uncertainty

290 abs(residuals), train models for uncertainty, estimate residuals, get weights (via weight-
 291 function) (problem of weight function -> we should norm the weights somehow since
 292 smoothing parameters are “dependent” on weights -> then, some outer points get really
 293 low weights (just because others in the middle have very little residuals and thus very high
 294 weight))

295 4.3 XXX Evaluation Method

296 yield estimation is a main goal. Claim that yield-estimation-accuracy is a objective mea-
 297 sure : - we have not looked at the yield so far - if the one NDVI-time-series predicts the
 298 yield better than a different one, we conclude that the first time-series carries more true
 299 information about the plants Now: "yield NDVI-TS / derived-covariates"

300 4.3.1 yield estimation

301 problem: high dimensionality and unequal duration/length -> use features
 302 name approaches for yield estimation (we will use a simple but flexible one)
 303 random forest ■ for evaluation out-of-bag estimates

²That is, we use all observations (in SCL45) but the current one.

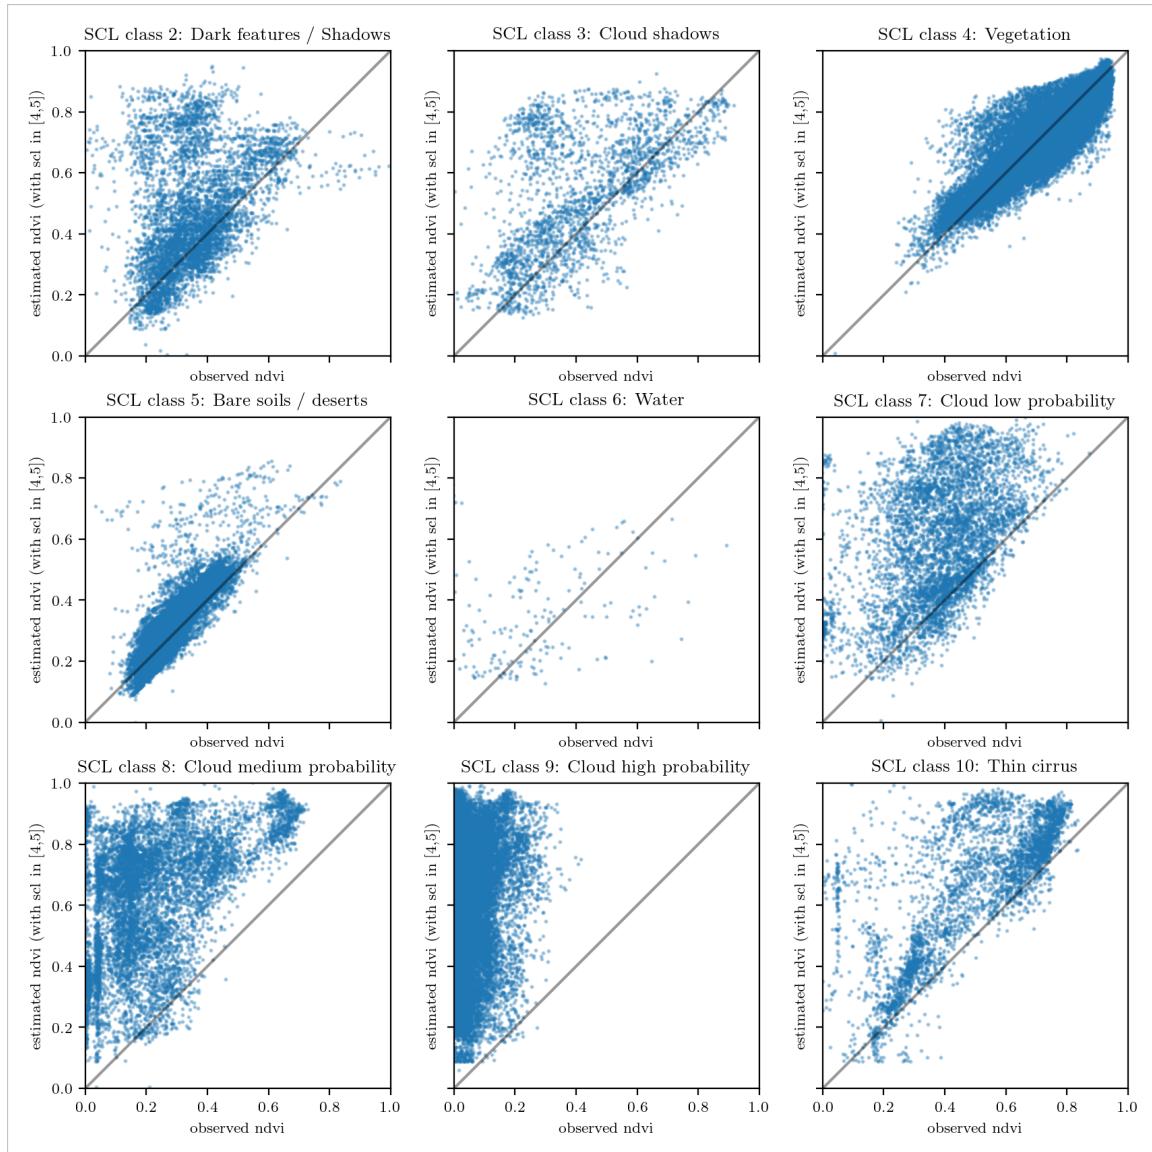

Figure 4.2: XXX caption XXX

304 Covariates used

305 reference to kamir et al, why we did choosed some and not others

306 **Chapter 5**

307 **Results**

308 **5.1 XXX small recap from “Interpolation Methods”**

309 **5.2 Robustification and NDVI-Correction**

Table 5.1: XXX RMSE of yield prediction

| | rf | lm-scl | lm-all | mars | gam | lasso | no-correction |
|--------|-------|--------|--------|-------|-------|-------|---------------|
| ss | 1.999 | 1.872 | 1.829 | 2.055 | 2.047 | 2.033 | 1.941 |
| dl | 1.873 | 1.886 | 1.896 | 1.988 | 1.898 | 1.833 | 2.018 |
| ss-rob | 1.895 | 2.010 | 2.037 | 1.970 | 1.874 | 1.928 | 1.880 |
| dl-rob | 1.865 | 1.884 | 2.002 | 1.996 | 1.808 | 1.875 | 2.005 |

310 **Chapter 6**

311 **Discussion**

312 **High RMSE in ...:** How much can we expect to get? We have multiple sources of uncer-
313 tainty in the data: 1. Uncertainty in Yield data collected by the combine harvester 2.
314 Uncertainty in Yield data through rasterization 3. Uncertainty in satellite images through
315 “measurement errors” introduced via clouds and other atmospheric effects 4. Uncertainty
316 introduced by interpolating (especially when long data-gaps are present)

317 **Chapter 7**

318 **Outlook**

319 **7.1 Data**

- 320 — Method how data has been extrapolated to the grid could possibly be improved
321 — For computational reasons we mostly considered all years and split the data (on the
322 pixel level) randomly into a train/test set. A cross Validation with leaving one year
323 out would be

324 **7.2 Interpolation**

- 325 — Penalized Regressions as described in ... are similar to smoothing splines (c.f. ...)
326 but different. Better?

327 **7.3 NDVI Correction**

- 328 — try different link functions in section ... between estimated absolute residuals and
329 weights

330 **7.4 NDVI Correction + +**

- 331 — NDVI Correction can be applied to all sorts of land observed via. satellites (without
332 the need of ground truth data)
333 — The idea of NDVI Correction could be applied to other spectral indices like the
334 Green Leaf Area Index.
335 — Yield is not the only target variable of interest. Other variables like protein content
336 could also be used in section ... for the method evaluation.
