Notation

```
c: a (vector of) constant(s)
\lambda \in \mathbb{R}: a scalar
n \in \mathcal{N}: sample size
i, j are indices in \{1, \ldots, n\}
x \in \mathbb{R}^n: covariable in 1-dim interpolation setting
w \in \mathbb{R}^n: a vector of weights for each location x
y \in \mathbb{R}^n: response in 1-dim interpolation setting
\hat{y} \in \mathbb{R}^n: estimate of y
r \in \mathbb{R}^n: residuals given by y - \hat{y}
Pixel: A pixel describes a specific location in a field. It has the size of 10 x 10 meters
and coincides with the resolution (and location) of the sentinel-2 pixels. Such pixels are
illustrated in figure ??.
P_t: this describes the observed data (weather and spectral bands) at pixel P and at time
P: a pixel. More formally we see it as a collection of all the observations at the specified
location within one season.
SCL: scene classification layer. This indicates what one can expect at a pixel at a sampled
time. For an overview c.f. table 2.1
P^{SCL45}: similar to P but we only consider observations which belong to the classes 4 and
5. This is used done to get a subset of observations which are less contaminated by clouds
and shadows.
NDVI: normalized vegetation difference index
DAS: days after sowing
GDD: growing degree days – cumulative sum of (temperature – threshold)<sup>+</sup>
```

78 XXX

Interpolation Methods

- In this section, we take a closer look at several interpolation methods, which will be used
- 82 to interpolate and smooth the NDVI time series.
- 83 First, we give a brief overview in table 3.1.
- 84 Second, we define the general setting and discuss a general approach to make the interpo-
- lation more robust (i.e. reduce the impact of outliers).
- 86 Later, we introduce and discuss each method.
- 87 Then, we try to extract the main ingredients of each method to forge our own one.
- 88 Finally, using leave-one-out cross validation, we tune the parameters (where necessary)
- and get a first idea of the performance of each method.

3.1 Setting

We are given data in the form of (x_i, Y_i) for i = 1, ..., n). Assume that it can be represented by

$$Y_i = m(x_i) + \varepsilon_i$$

where ε_i is some noise and $m: \mathbb{R} \to \mathbb{R}$ being some (parametric or non-parametric) function. If we assume that $\varepsilon_1, \ldots, \varepsilon_n$ i.i.d. with $\mathbb{E}[\varepsilon_i] = 0$ then

$$m(x) = \mathbb{E}[Y \mid x]$$

Different assumptions on m will lead to the following methods:

2 3.2 Robustify

- Now we discuss a general approach of how to robustify an interpolation. The main idea
- 94 is to give less weight to observations which have high residuals after the initial (or if we
- reiterate, the last) fit.
- 96 Even though the procedure is taken from the robust version of the LOESS smoother (c.f.
- section 3.4.4 and Cleveland (Cleveland)), we discuss it now because we will apply it also
- to other interpolation methods.

3.2 Robustify 4

Table 3.1: A short summary of the studied interpolation methods

8	${f assumtpions}$	pros	cons	weights	bounded
Golay filter	high frequencies - are noise (low.pass filter) equidistant points local polynomials		cannot deal natively with missing data (need some interpolation)	no	mostly
NDVI –	vegetation cannot grow faster than some slope	- biological knowl edge	bad "upper envelope" since weights are not used for the estimation itselfe	(no)	mostly
Loess –	local polynomial - with points closer - to the estimated point are more important		- computationally expensive	yes	mostly
Splines	function is integrable	- intuitive meaning - of penalty - general assump- tions - flexible shape		yes	no
	function can be approximated by a linear combination of B-splines basis functions	general assumtion - flexible shape -	unbounded no intuitive meaning for smoothing		no
(Gaussian) Kernel Smooth- ing		- simple - - general assump- tions	- bandwidh: failes if there are big data- gaps	yes	yes
Logistic	function first in-creases then decreases ndvi has a minimal value		parameterestimation can go seriously wrong strange behaviour for long data-gaps		mostly
Universal – Kriging	realization of a	- informative pa rameters - flexible -	regression to the mean assumptions clearly not met	yes	mostly

XXX^{1}

Before we describe the procedure, we define a function which will determine the weight given to each observation such that observations with large scaled residuals will have less weight. That is the bisquare function B:

$$B(x) := \begin{cases} \left(1 - x^2\right)^2, & \text{if } |x| < 1\\ 0, & \text{else} \end{cases}$$

Now, we do something similar to what is done in iteratively reweighted least squares. After an initial interpolation, update the weights of each observation with

$$w_i^{\text{new}} := w_i^{\text{old}} \operatorname{B} \left(\frac{|r_i|}{6 \operatorname{mad} (r_1, \dots, r_n)} \right)$$
 (3.2.0.1)

where $r_i = y_i - \hat{y}_i$ denotes the residuals. We can iterate this reweighting and stop after several steps or when the change of the values is smaller than some tolerance.

04 Examples of such iterative fits are illustrated in the figures 3.4 3.5, 3.6, 3.4 and 3.7.

3.2.1 XXX Our Adjustment:

Since we usually observe outliers with negative residuals we decide to divide the negative residuals by two before updating the weights. Furthermore, we want to prevent low-weighted observations to corrupt our estimation of scale (the median) and thus we use the weighted median. This can be defined as

$$\operatorname{med}_{\operatorname{weighted}}(r, w) := \underset{\lambda \in \mathbb{R}}{\operatorname{arg\,min}} \sum_{i=1}^{n} |r_i w_i - \lambda|$$

for $r, w \in \mathbb{R}^n$

3.3 Parametric Regression

Parametric Curve estimation tries to fit a parametric function (e.g. a Gaussian function with parameter μ and σ) to a dataset. In the following, we introduce 2 such parametric approaches.

Optimization Issues

Since we aim to minimize the residuals sum of squares over 5 (or 6) parameters, we try to solve a non-convex optimization problem. Thus, the algorithm² either struggles to find the global minimum or fails to converge. This was fixed by providing for each parameter reasonable initial values and generous bounds (which match our experience).

¹Note that due to using the median for the normalization, we gain a breakdown point of 50% for outliers in u

 $^{^{2}\}mathrm{We}\ \mathrm{used}\ \mathrm{the}\ \mathrm{python}\ \mathrm{function}\ \mathtt{scipy.optimize.curve_fit}$

3.3.1 Double Logistic

The Double Logistic smoothing as described in Beck, Atzberger, Høgda, Johansen, and Skidmore (Beck et al.) heavily relies on shape assumptions of the fitted curve (i.e. the NDVI time series).

20 Assumptions:

- There is a minimum NDVI level Y_{\min} in the winter (e.g. due to evergreen plants), which might be masked by snow. This can be estimated beforehand, taking into several years into account.
 - The growth cycle can be divided into an increase and a decrease period, where the time series follows a logistic function. The maximum increase (or decrease) is observed at t_0 (or t_1) with a slope of d_0 (or d_1).

The equation of the double-logistic fit is given by:

$$Y(t) = Y_{\min} + (Y_{\max} - Y_{\min}) \left(\frac{1}{1 + e^{-d_0(t - t_0)}} + \frac{1}{1 + e^{-d_1(t - t_1)}} - 1 \right)$$

- Where the five free parameters: Y_{max} , d_0 , d_1 , t_0 , t_1 are initially estimated by least squares. Such fit can be seen in figure 3.1.
- Similar as for the Savitzky-Golay Filter (c.f. section 3.4.3) we reestimate (only once) the parameters by giving less weight to the overestimated observations and more weight to the underestimated observations³.

Pros	Cons
 Incorporates subject specific knowledge in the case of evergreen plants covered 	— Strong shape assumptions on the NDVI curve.
in snow.	— Parameter optimization might go
 Optimized parameters have an intuitive meaning. 	wrong. This can be mitigated to some extent to provide bounds for the parameters
	— Strange behavior in regions with little observations. (cf. figure 3.1)

3.3.2 Fourier Approximation

Similar as in section 3.3.1 we fit a parametric curve to the data by least squares. Here we take the second order Fourier series:

$$NDVI(t) = \sum_{j=0}^{2} a_j \times \cos(j \times \Phi_t) + b_j \times \sin(j \times \Phi_t)$$

where $\Phi = 2\pi \times (t-1)/n$.

³For the details on the weights we refer to Beck, Atzberger, Høgda, Johansen, and Skidmore (Beck et al.)

Pros Cons

- Assumption of periodicity can be helpful if we are modelling multiyear grow cycles
- Flexible curve shape

- Bad behavior in regions with little data (cf. figure 3.1)
- Hard to interpret estimated parameters
- Parameter estimation can go wrong. Introducing bounds can help.

Figure 3.1: Here we observe the nice fitting possibilities of the two parametric methods but notice also some misbehavior

3.4 Non-Parametric Regression

In non-parametric curve estimation, we no longer demand our curve to be fully determined by several parameters, but we allow it to also dependent on the data. That said, we might still use some tuning-parameters sometimes.

3.4.1 Kernel Regression

As described previously, we would like to estimate

$$\mathbb{E}[Y \mid X = x] = \int_{\mathbb{R}} y f_{Y|X}(y \mid x) dy = \frac{\int_{\mathbb{R}} y f_{X,Y}(x,y) dy}{f_{X}(x)},$$
(3.4.1.1)

where $f_{Y|X}, f_{X,Y}, f_X$ denote the conditional, joint and marginal densities. This can be done with a kernel K:

$$\hat{f}_X(x) = \frac{\sum_{i=1}^n K\left(\frac{x-x_i}{h}\right)}{nh}, \hat{f}_{X,Y}(x,y) = \frac{\sum_{i=1}^n K\left(\frac{x-x_i}{h}\right) K\left(\frac{y-Y_i}{h}\right)}{nh^2}$$

By plugging the above into equation 3.4.1.1 we arrive at the *Nadaraya-Watson* kernel estimator:

$$\hat{m}(x) = \frac{\sum_{i=1}^{n} K((x - x_i)/h) Y_i}{\sum_{i=1}^{n} K((x - x_i)/h)}$$

Examples: Normal, Box For local bandwidth selection see Brockmann et al. (1993)
XXX

Pros Cons

- flexible due to different possible kernels
- can be assigned degrees of freedom (trace of the hat-matrix)
- estimation of the noise variance $\hat{\sigma}_{\varepsilon}^2$ (XXX c.f. CompStat 3.2.2)
- if the $x \mapsto K(x)$ is not continuous, \hat{m} isn't either
- choice of bandwidth, especially if x_i are not equidistant.

Kriging 3.4.2

Kriging was developed in geostatistics to deal with autocorrelation of the response variable at nearby points. By applying the notion that two spectral indices which are (timewise) close should also take similar values, we justify the application of Kriging. In the end, we would like to fit a smooth Gaussian process to the data. For this subsection, we will follow Diggle and Ribeiro (dig).

Definitions and Assumptions

A Gaussian Process $\{S(t): t \in \mathbb{R}\}$ is a stochastic process if $(S(t_1), \ldots, S(t_k))$ has a multivariate Gaussian distribution for every collection of times t_1, \ldots, t_k . S can be fully characterized by the mean $\mu(t) := E[S(t)]$ and its covariance function $\gamma(t, t') = \text{Cov}(S(t), S(t'))$

Assumption: We will assume the Gaussian process to be stationary. That is for $\mu(t)$ to be constant in t and $\gamma(t,t')$ to depend only on h=t-t'. Thus, we will write in the following only $\gamma(h)$.

We also define the variogram of a Gaussian process as

$$V(h) := V(t, t+h) := \frac{1}{2} \operatorname{Var}(S(t) - S(t+h)) = (\gamma(0))^2 (1 - \operatorname{corr}(S(t), S(t+h)))$$

And decide to use a Gaussian Variogram defined by

$$V(h) = p \cdot \left(1 - e^{-\frac{h^2}{\left(\frac{4}{7}r\right)^2}}\right) + n,$$

where h is the distance, n is the nugget, r is the range and p is the partial sill visualized in figure $3.2.^5$

Pros	Cons
— It is a well-studied method.	— Regression to the mean.
— Parameters have an intuitive meaning.— Flexible covariance structure.	 Violated assumption of constant mean and constant variance. Thus, the NDVI is not a stationary process.
	— Skewness of errors is not taken into ac-

⁴Note that the process is also isotropic (i.e. $\gamma(h) = \gamma(||h||)$ since we are in a one-dimensional setting and the covariance is symmetric.

count.

⁵Strictly speaking we use a scaled version of the variogram. Thus, only the ratio of p/n matters.

Figure 3.2: Gaussian Variogram with nugget=1, partial sill=3, range=55

Figure 3.3: On the left, we see how the interpolation change if we increase the nugget and the range parameter. On the right we compare two kriging interpolations, where one takes parameters by numerically maximizing the (which results in a very small nugget) and the other takes the median of many such numerical optimizations.

3.4.3 Savitzky-Golay Filter (SG Filter)

The Savitzky-Golay Filter, introduced in Savitzky and Golay (Savitzky and Golay) is a technique in signal processing and can be used to filter out high frequencies (low-pass filter) as argued in Schafer (Schafer). Furthermore, it also can be used for smoothing by filtering high frequency noise while keeping the low frequency signal. First, we choose a window size m. Then, for each point, $j \in \{m, m+1, \ldots, n-m\}$ we fit a polynomial of degree k by:

$$\hat{y}_j = \min_{p \in P_k} \sum_{i=-m}^m (p(x_{j+i}) - y_{i+j})^2,$$

where P_k denotes the Polynomials of degree k over \mathbb{R} .

For equidistant points this can efficiently be calculated by

$$\hat{y}_j = \sum_{i=-m}^m c_i y_{j+i},$$

where the c_i are only dependent on the m and k and are tabulated in the original paper.

Adaptation to the NDVI

In a rather famous paper Chen, Jönsson, Tamura, Gu, Matsushita, and Eklundh (Chen et al.) a "robust" method based on the Savitzky-Golay has been used. The method is based on the assumption that due to atmospheric effects the observed NDVI tends to be underestimated and that it cannot increase too quickly⁶.

Algorithm:

- i.) Remove points which are labeled as cloudy.
- ii.) Remove points which would indicate an increase greater than 0.4 within 20 days.
- iii.) Linearly interpolate to obtain an equidistant time series X^0 .
 - iv.) Apply the Savitzky-Golay Filter to obtain a new time series X^1 .
 - v.) Update X^1 by applying again a Savitzky-Golay Filter. Repeat this until $w^T | X^1 X^0 |$ stops decreasing, where w is a weight vector with $w_i = \min \left(1, 1 \frac{X_i^1 X_i^0}{\max_i \|X_i^1 X_i^0\|} \right)$. This reduces the penalty introduced by outliers⁷ and by repeating this step we approach the "upper NDVI envelope".

Pros Cons

- Popular technique in signal processing.
- Efficient calculation for equidistant points.
- Upper envelope matches intuition for the NDVI. Therefore, it is robust against outliers with small values.
- No natural way of how to estimate points which are not in the data.
- Not generalizable to other spectral indices.
- Linear interpolation to account for missing data might be not appropriate.
- No smooth interpolation between two measurements.

Extension: Spatial-Temporal-Savitzky-Golay Filter

One notable adaptation of the Savitzky-Golay is the presented by Cao, Chen, Shen, Chen,

Zhou, Wang, and Yang (Cao et al.). The key difference is the additional assumption of the

cloud cover being discontinuous and that we can improve by looking at adjacent pixels⁸.

8 Because we are working with rather high resolution satellite data, and we need the variance

9 in the predictors, we will waive this extension.

3.4.4 Locally Weighted Regression (LOESS)

Introduced by: Cleveland (Cleveland) implemented here Cappellari, McDermid, Alatalo, Blitz, Bois, Bournaud, Bureau, Crocker, Davies, Davis, de Zeeuw, Duc, Emsellem, Khochfar, Krajnović, Kuntschner, Morganti, Naab, Oosterloo, Sarzi, Scott, Serra, Weijmans, and Young (Cappellari et al.)

⁶The latter is argued by the biological impossibility of such fast vegetation changes

⁷Here we call a point *i* an outlier if $X_i^0 < X_i^1$.

⁸Here, we say that a pixel is adjacent if it is the same pixel but from a different year (keeping the same day of the year) or (if not enough of such temporal-adjacent pixel are found) it is spatially adjacent

The Locally Weighted Regression (LOESS) can be understood as a generalization of the Savitzky-Golay Filter (c.f. sec. 3.4.3).

Given a proportion $\alpha \in (0,1]$, we estimate each y_i separately by fitting a polynomial of order d by weighted least squares. The weights are (usually) defined by

$$w_i(x_j) = \begin{cases} \left(1 - \left(\frac{x_j}{h_i}\right)^3\right)^3, & \text{for } |x_j| < h_i \\ 0, & \text{for } |x_j| \geqslant h_i \end{cases}$$

where h_i is the minimal distance such that $\lceil \alpha n \rceil$ observations are in the ball $B_{h_i}(x_i)$. So for each y_i we only consider a proportion α of the observations.

How does the Robust LOESS differ from the SG Filter?

The LOESS smoother takes a fraction of points instead of a fixed number and therefore automatically adapts to the size of the data we wish to interpolate. However, we run into the danger of considering too little observations, since the estimation breaks down if $\lceil \alpha n \rceil < d+1$. Furthermore, LOESS gives less weight to points further away. This yields a "smoother" estimate, since when we slide the window (e.g. for estimating the next value) an influential point at the border does not suddenly get zero weight from being weighted equally before. Finally, the LOESS also can be used for non-equidistant data and allows for arbitrary interpolation.

Figure 3.4: The LOESS smoother fitted to different (SCL45) NDVI time series. Iterations of a robustifing refit (as indicated in section 3.2) are also displayed

⁹If too many weights are set to zero, we might end up considering not enough observations and thus get a singular design-matrix (for the least squares estimation). Therefore, we substitute h_i with $1.01h_i$, so that the observation on the boundary of $B_{h_i}(x_i)$ does not get completely ignored.

Pros	Cons
 Flexible generalization of Savitzky- Golay 	to surprising estimates (no smoothness
— arbitrary interpolation possible	guarantees for the second derivative)
— Intuitive parameters	— Multiple XXXXXXx

3.4.5 B-splines

from Lyche and Morken (Lyche and Morken)

$$S(x) = \sum_{j=0}^{n-1} c_j B_{j,k;t}(x)$$

$$B_{i,0}(x) = 1, \text{ if } t_i \le x < t_{i+1}, \text{ otherwise } 0$$

$$B_{i,k}(x) = \frac{x - t_i}{t_{i+k} - t_i} B_{i,k-1}(x) + \frac{t_{i+k+1} - x}{t_{i+k+1} - t_{i+1}} B_{i+1,k-1}(x)$$

Smoothing: We can relax the constraint that we have to perfectly interpolate. Thus, we use the minimum number of knots¹⁰ such that: $\sum_{i=1}^{n} (w(y_i - \hat{y}_i))^2 \leq s$

— can be assigned degrees of freedom — smooth	
— performs also well if points are not ing splin	ng process does not translate interpretation (unlike smoothes) smoothing parameter s

3.4.6 Natural Smoothing Splines

Let \mathcal{F} be the Sobolev space (the space of functions of which the second derivative is integrable). Then the unique¹¹ minimizer

$$\hat{m} := \underset{f \in \mathcal{F}}{\operatorname{arg \, min}} \sum_{i=1}^{n} (Y_i - f(x_i))^2 + \lambda \int f''(x)^2 dx$$

is a natural¹² cubic spline (i.e. a piecewise cubic polynomial function). The objective function has an intuitive meaning, as to avoid lateral acceleration it is desirable to move the steering wheel as little as possible, when driving a car.

3.4.7 XXX Whittaker Smoother

XXX

 $^{^{10}}$ SciPy uses FITPACK and DFITPACK, the documentation suggests that smoothness is achieved by reducing the number knots used

¹¹Strictly speaking it is only unique for $\lambda > 0$

¹²It is called natural since it is affine outside the data range $(\forall x \notin [x_1, x_n] : \hat{m}''(x) = 0)$

Pros

— can be assigned degrees of freedom (trace of the hat-matrix)

— efficient estimation (closed form solution)

— intuitive penalty (we don't want the function to be too "wobbly" — change slopes)

— performs also well if points are not equidistant

— fixes the Runge's phenomenon (fluctuation of high degree polynomial interpolation)

3.5 Tuning parameter estimation

- 208 lots of cross validation
- what is the best? RMSE is bad, since we know that outliers are present optimizing w.r.t different statistics
- 211 ?plot with different denisties for each statistic

3.6 Robustification – Recap

- introduced in section ?? we want to review it
- robustifieng from loess -> lets try it with all. Result in figures ...
- 215 issues when reiterating often (we lose some points completely)
- 216 from pictures ... we get that one

3.6.1 Upper Envelope Approach - Penalty for negative residuals

discussion of idea, and explenation why we did no use it (arbitrary choice)

3.7 Performance Assecement

20 TEMP — Figures

Table 3.2: Performance comparison of different interpolation methods measured with various statistics. Considering only SCL45 points, we get the out-of-bag estimates using the given interpolation method. Consequently, we compute the absolute (value of the) residuals and apply the given statistic to it.

NDVI Correction / Improve NDVI Data

Let's remind ourselves that the data from the Sentinel-2 is equipped with a scene classification layer (SCL) and we therefore have some information of what is observed at each pixel for each sampled time (c.f. table 2.1). In this chapter we would like to improve the observed NDVI values by using more information than just the two bands used to calculate the NDVI (B4 and B8).

4.1 Considering other SCL Classes

In figure 4.1 we see for example that some blue points¹ follow the interpolated line closely and that they might be useful in improving an interpolation fit.

Figure 4.1: A smoothing splines fit considering green and yellow points (SCL45)

To get an impression whether there is some useful information contained in the remaining SCL-classes (all except 4 and 5) we would like to compare the observed NDVI with the

¹The blue points correspond to the SCL-class 10: Thin cirrus clouds

true NDVI. But since we do not have any ground truth data, we will make the following assumption:

Definition 4.1.0.1. XXXAssumption (true NDVI) The true NDVI value at time t can be successfully estimated by out-of-bag interpolation using high quality observations. That is the interpolated value (using XXX) considering the points $P^{SCL45} \setminus P_t$. In the following, we will call this estimate the "true"-NDVI

i.) For each pixel and for each observation (every SCL-class): estimate the NDVI value (via out-of-the-box interpolation²)

ii.)

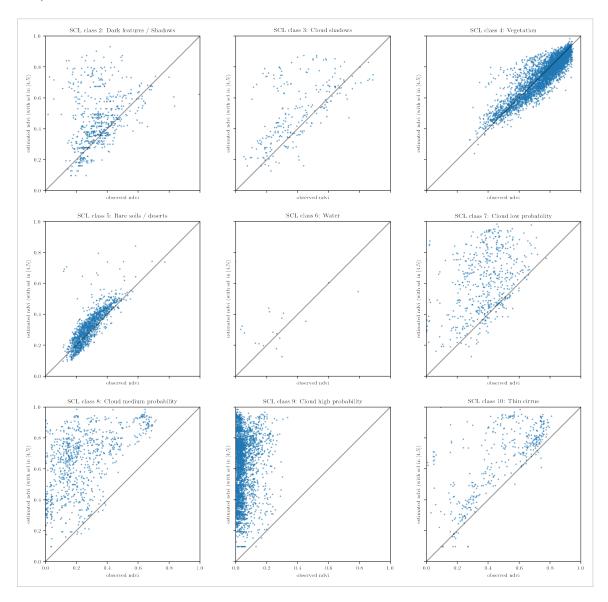

Figure 4.2: XXX caption XXX

²That is, we use all observations (in SCL45) but the current one.

4.2 XXX Correction 19

Table 4.1: XXX RMSE of yield prediction

	rf	lm-scl	lm-all	mars	gam	lasso	no-correction

roadmap ...

47 4.2.1 xxx idea -and- stepwise plots

4.2.2 xxx data-table-construction

249 xxx discussion about choosen covariates: list of things we considered but rejected + rea-250 soning

4.2.3 xxx ml-methods

4.3 xxx Evalutation Method

yield estimation is a main goal. Claim that yield-estimation-accuracy is a objective measure: - we have not looked at the yield so far - if the one NDVI-time-series predicts the yield better than a different one, we conclude that the first time-series carries more true information about the plants Now: "yield NDVI-TS / derived-covariates"

257 now we will discuss how to perform the yield estimation

4.3.1 yield estimation

- 259 problem: high dimensionality and unequal duration/length -> use features
- name approaches for yield estimation (we will use a simple but flexible one)
- 261 random forest for evaluation out-of-bag estimates

Covariates used

reference to kamir et al, why we did choosed some and not others
